Content

- ▶ Overview
- ▶ Approaches
- ▶ Pros and cons
- ▶ conclusions

Overview

- ▶ Engineers must demonstrate that no cracking occurs during the adiabatic process.
- ▶ Limited information, time, and budget are available for the analysis.
- ▶ Analyses are often commissioned by contractors or subcontractors.

Example to demonstrate

- ▶ Bunker silo wall
- ▶ 14 m long wall 5 meter high and 1.8 m thick
- ▶ Assumed adiabatic rise of 40 reaching 60°C
- ▶ Restrained horizontal bedding stiffness of gravel

approaches

- ▶ Common
 - ▶ 2D plane strain
 - ▶ 2.5D plane stress
- ▶ Less common
 - ▶ 2.5D plane stress extended model
 - ▶ 3D model

2D plane strain

- ▶ Fast approach in modelling time.
- ▶ Strain out of plane being 0 means high out of plane stresses.
- ▶ Progressive in heating up and conservative in cooling down

2D plane stress

- ▶ Fast approach in modelling time.
- ▶ Stress out of plane is 0
- ▶ Only in plane stress is checked.
- ▶ Progressive in all cases

2.5D plane stress

- ▶ (Fast) approach in modelling time.
- ▶ Software tweaks the out of plane stiffness.
 - ▶ Constant rotation of the plane (straight)
 - ▶ A translation stiffness of 0 or a certain value.
- ▶ Out of plane stress reduced both, in the young heating phase as in the cooling phase (a bit more realistic).

2.5D plane stress extended model

- ▶ (Reasonable Fast) approach in modelling time.
- ▶ Real out of plane stiffness.
 - ▶ No constant rotation of the plane (realistic)
 - ▶ Realistic translation stiffness
- ▶ Out of plane stress correctly reduced both, in the young heating phase as in the cooling phase.

3D volume model

- ▶ (Slowest) approach in modelling time.
- ▶ Real out of plane stiffness.
 - ▶ No constant rotation of the plane (realistic)
 - ▶ Realistic translation stiffness
- ▶ Realistic behaviour over the entire model

Comparison temperature

Comparison displacements

- Only 2.5D extended and 3D modelling can give realistic out of plane deformations.

LINEAR
wand - Steps, Time-step 322, Time 0.34560E+07
Displacements TDtX
min: -0.14mm max: 0.00mm

LINEAR
wand - Steps, Time-step 322, Time 0.34560E+07
Displacements TDtY
min: -0.85mm max: 0.00mm

Comparison stress

- ▶ 2D overshoots the out of plane stresses (safe, but not sustainable)
- ▶ 2.5D straight plane undershoots stresses, this is not a safe approach.
- ▶ 2.5D extended and 3D modelling give comparable realistic output.

Creep and Relaxation in time

- ▶ Depending on different parameters this can be a positive or negative effect.
- ▶ Negative in the first phase where compression is lowered
- ▶ Positive in the next phase reducing tensile stress

Conclusions

- ▶ 2D plane strain overestimate the stresses. Fast, but not economical/sustainable
- ▶ 2.5D straight plane underestimate the stresses, Could be unsafe.
- ▶ 2.5D extended model is the most optimal modelling approach.
- ▶ 3D modelling is necessary in cases of non-orthogonal shapes or clashing/connection shapes. A difficult geometry can be taken into account in a realistic way.

These models can also be used for predicting real crack widths instead of just a unity check on the $F_{tu}/\text{crackindex}$.

The effect of reinforcements can be taken into account. In that approach also hybrid, steel fibers in combination with traditional reinforcements (SFRC) can lead to less crack widths and avoidance of unnecessary use of cooling pipes. It can minimise the environmental impact in a project, which is an important factor in our point of view.

- ▶ Creep and relaxation is very important to get more realistic behaviour. Without relaxation the stresses and the crack index will be overestimated which could lead to wrong predictions and therefor modification of the design or even cooling options.

15-20 min is too short to elaborate

- ▶ On cooling pipes
 - ▶ Positive effects and why to omit them
- ▶ On Steel fiber addition
 - ▶ We often encounter dense reinforcement zones where concrete can hardly be poured through.
 - ▶ Nonlinear design analysis can optimise the reinforcement.
 - ▶ Steel fibers in addition can reduce the normal amount of reinforcement and also help reducing crack risks in mass concrete structures.

Input parameters needed

► Concrete

- Adiabatic curve (CUR67 or NEN 12390)
- Tensile strength as function of maturity or time
- Creep in compression and tension (relaxation)
- Shrinkage autogenous and drying

Creep and Relaxation in time

- ▶ Creep function (compliance function J) for several ages concrete
- ▶ Stress reduction (creep, relaxation) for several time of loading
- ▶ Creep and relaxation via visco elasticity model with “Kelvin chains”
- ▶ The positive early compression stress upto day 2 is reduced with 50% on day 10, but negative cooling at day 3 with 35% at day 10.

Input parameters

- ▶ Boundaries
 - ▶ Convection as function of time (remove formwork etc)
- ▶ Temperature
 - ▶ Temperature seasonally and daily change

Zoomed in: Daily temperature

Checking criteria Temperature

Result		Description
T1	$T1 \leq 65$	Maximum core temperature
$\Delta T1$	$\Delta T1 \leq 20$	Maximum temperature difference between the core and the cover
$\Delta T2$	$\Delta T2 \leq 20$	Temperature difference between the core and the cover after demoulding
$\Delta T3$	$\Delta T3 \leq 20$	Temperature difference between the cover and the mean environment temperature

Checking Crack index

250212_DIANA_Rink_OWK_VT08_V3_LINEAR
Stort9Dak - Steps, Time-step 154, Time 296 day
Crack Indices F_{tu}
min: 0.00 max: 1.25

Fig. 17: UC scheur na 296 dagen, eindtijd, aangepaste legenda: $F_{tu} > 0.7$ in "rood"

Checking Stresses clarifies

250212_DIANA_Rink_OWK_VT08_V3_LINEAR
Stort9Dak - Steps, Time-step 154, Time 296 day
Cauchy Total Stresses SZZ
min: -5.53N/mm² max: 3.86N/mm²

Fig. 22: Spanning in Z-richting, SZZ na 296 dagen (eind), in verticale richting > 3.21 MPa

Checking criteria crack index

- ▶ UC crack = σ_1 / f_{ctm}
 - ▶ UC crack < 1.0 (3D random variation shrinkage and correct constraints)
 - ▶ UC crack < 0.7 (simpler models 2/2.5D straight planes).
 - ▶ UC crack < 0.5 (When Cooling pipes are added)

Why is not UC crack < 1.0 used? UC crack < 0.7 conservative?

- ▶ Use f_{ctm} not the higher “splejt treksterkte”
- ▶ Use f_{ctm} is function of time (maturity) conform Eurocode or tests.
- ▶ Check in extreme fiber or at the cover or pick a point on the screen?
- ▶ Allow 10% of cross section (outer fiber/cover) temporary above UC>1.
